## **Module 3 Cheatsheet: JavaScript Programming for Web Applications**

Class or Method	Description	Example
appendChild()	An HTML DOM method that after creating an element, you can use this function to place the element in the appropriate location within the document. The element to append is the only parameter.	<pre>//Creates the element  and text "Hello World". Appends Hello World  to the HTML document. <head></head></pre>
Arrays	Created by declaring the array elements in $[\ ]$ . An array can be assigned to a variable, usually using the keyword const or var. Arrays use zero based indexing to access their elements.	<pre>const Beatles = ["Ringo", "Paul", "George", "John"]; //Here Beatles[0] is "Ringo".</pre>
Date()	Constructor is new Date([optional parameters]). If the constructor is declared with no parameters, it returns current local date and time. New dates can be created by passing parameters to new Date function.	<pre>//create a new date from a string var newDate = new Date("2021-1-17 13:15:30");  //create a new date instance representing 17 Jan 2021 00:00:00 //note that the month number is zero-based var newDate = new Date(2021, 0, 17);</pre>
document.createElement()	Takes one tag name parameter and creates an element with that name. Can place the element elsewhere on the page using functions like insertBefore(), appendChild(), replaceChild().	<pre>//Creates the element  and text "Hello World". Appends Hello World  to the HTML document. <head></head></pre>
document.createTextNode()	Takes a string as input text and returns a text node with the input text.	<pre> //Creates the element  and text "Hello World". Appends Hello World  to the HTML document. <head></head></pre>
<pre>document.getElementByID()</pre>	A method of the DOM that takes an ID value parameter and returns an element that matches the id.	<pre> //Changes the content of the div to "Hello World!" <div id="div1"></div></pre>
document.getElementsByTagName()	A method of the DOM that takes a tag name parameter and returns an array called "NodeList" that contains elements with the specified tag name.	<pre>//c/script&gt; //Gets an array of all elements in a document with the  tag. var tagNameArray = document.getElementsByTagName("p");</pre>
document.write()	Writes HTML or JavaScript to a document. Note that it overwrites any other text in the document so is mostly used for testing purposes only.	<pre>//Writes "Hello World" to the output stream. document.write("Hello World");</pre>
element.getAttribute()	Returns the value of the specified attribute. Takes one parameter: the attribute name whose value is to be returned.	<pre>//Removes the CSS style color blue <div id="div1" style="color: blue"></div> <script>   var div1 = document.getelementById("div1").getAttribute("style"); </script> //Changes the content of the div to "Hello World!" <div id="div1"></div></pre>
element.innerHTML()	A property of the Element class that returns or alters contents of an HTML element as a text string.	<pre>Hello Hello   document.getElementById("div1").innerHTML = "Hello World!</pre>
element.removeAttribute()	A property of the Element class that removes all previously set inline CSS styles for a particular element. Takes one parameter: the attribute name that is being removed.	";  //Removes the CSS style color blue <div id="div1" style="color: blue"></div> <script></td></tr></tbody></table></script>

about:blank 1/2

10/27/24, 4:34 PM about:blank

```
var div1
                                                                                               document.getelementById("div1").getAttribute("style");
                                  A property of the Element class that overwrites all previously
                                                                                               //In all elements named "theImage" sets the name of all src
                                  set inline CSS styles for a particular element. Takes two
                                                                                               attributes to "another.gif"
element.setAttribute()
                                                                                               document.getElementById("theImage").setAttribute("src",
                                  parameters: the attribute name that is being set and the
                                                                                               "another.gif");
                                  attribute value the attribute is set to.
                                                                                               //Changes the CSS style color from blue to red
                                                                                               <div id="div1" style="color: blue"></div>
                                  A property of the Element class that returns or alters inline
                                                                                               <script>
element.stvle()
                                                                                                var div1 = document.getelementById("div1");
div1.style.color = "red";
                                  CSS. Syntax is element.style.propertyName = value
                                                                                               </script>
                                  Instance creates two properties about the error: message that
                                                                                               //Catch statement defines a block of code to be executed if an
                                  contains description of the error and the name property
                                                                                               error occurs in the try block.
                                  identifies the type of error. Generic error plus 6 other core
                                                                                               catch (err) {
                                  errors: TypeError, RangeError, URIError, EvalError,
Error Objects
                                                                                                document.getElementById("myfile").innerHTML = err.name;
                                  ReferenceError, SyntaxError.
                                                                                               //Creates custom error message
                                  Error object can be extended to create custom error messages
                                                                                               throw new Error("Only values 1-10 are permitted");
                                  using the throw keyword.
                                  The history object is part of the window object and contains
                                  the URLs visited by the user within a browser window. It
                                                                                               //Go back two pages if the history exists in the history list.
                                  exposes useful methods and properties that let you navigate
History Objects
                                                                                               history.go(-2);
                                  back and forth through the user's history and manipulate the
                                  contents of the history stack.
                                                                                               //Creates a new  element and places it in the elementList
                                  An HTML DOM method that, after creating an element,
                                                                                               before the first child of 
                                  places a child element in the appropriate location before an
                                                                                               let newLI = document.createElement("li");
insertBefore()
                                                                                               newLI.innerText = "new Element";
                                  existing child. The method takes two parameters, the node
                                                                                               let elementList = document.getElementById("thisList");
                                  object to be inserted and the existing node to insert before.
                                                                                               elementList.insertBefore(newLI, elementList.childNodes[0]);
                                                                                               //Returns the hostname property
                                  The location object is part of the window object and contains
Location Objects
                                                                                               let myhost = location.hostname;
                                  information about the current URL.
                                                                                               newLI.innerText = "new Element";
                                  The navigator object is part of the window object class in the
                                  DOM that represents the client Internet browser, also called
                                                                                               //Retrieves the name of the browser
Navigator Objects
                                  the user agent. There is no standard for this object so what it
                                                                                               var browsername = navigator.appName;
                                  returns differs from browser to browser.
                                                                                               //Executes myFunction after MyHTMLPage has been loaded
onload()
                                  A DOM event that starts a method when a page is loaded.
                                                                                               document.getElementById("MyHTMLPage").onload = function ()
                                                                                               {myFunction};
                                                                                               //Creates a new node and replaces the second element in
                                                                                                thisList" with the word "blue"
                                  After creating an element, this function replaces a child node
replaceChild()
                                                                                               let secondBullet = document.createTextNode("blue");
                                  with a new node.
                                                                                               var myList = document.getElementById("thisList").childNodes[1];
                                                                                               myList.replaceChild(secondBullet,
                                                                                                                                     myList.childNodes[1]);
                                  The screen object is part of the window object class in the
                                                                                               //Returns the height and width of the user's screen
Screen Objects
                                  DOM that can be used to return properties about the user's
                                                                                               var height=screen.height;
                                                                                               var width=screen.width;
                                  screen
                                  The DOM window object is at the top of the DOM hierarchy
                                  and serves as the global object. Everything in the DOM takes
                                                                                               //Opens a new browser window with the specified URL
Window Objects
                                  place in a window. The window object controls the
                                                                                               window.open("http://www.w3schools.com");
                                  environment that contains the document.
                                  Opens a new window. The first parameter is a path, a URL, or
                                  an empty string, and optional parameters include the window
                                  name, features such as the placement of the window or the
                                                                                               //Opens a new window that opens the IBM home page and has a
                                  dimensions, and a Boolean replace value. The feature
                                                                                               width of 600 and a height of 800)
                                  parameter is a comma separated string of name-value pairs
window.open()
                                                                                               let thisWindow = window.open("http://www.ibm.com", "myWindow",
                                  and the replace parameter is an optional Boolean. This
                                                                                               "width"=600, "height"=800);
                                  parameter has been deprecated so modern browsers may not
                                  support it. This method returns a reference to the new window
                                  object.
                                  Scrolls to a particular place in a window. Parameters include
                                                                                               //Scrolls the window to the pixel located at the coordinate
window.scrollTo()
                                  the x-coordinate which is the left-most pixel and the y-
                                                                                               (20, 200)
                                                                                               window.scrollTo(20, 200);
                                  coordinate which is the upper-most pixel.
                                                                                               //Enables the use of properties and methods of the String class
                                                                                               such as the property n.length
                                                                                               let n = new String ("abc");
                                  Primitive types can be converted to objects using wrapper
                                  objects. They are the same name as the primitive except they
Wrapper Objects
                                                                                               //Returns string
                                  start with uppercase letter. The typeof keyword returns a
                                                                                               typeof "abc";
                                  string indicating the data type of the operand.
                                                                                               //Returns object
```

about:blank 2/2

typeof new String("abc");
